# Motivation for Semidefinite Programming

- Linear Programming is a common constrained optimization technique with uses in:
  - Math
  - Computer Science
  - Economics
  - Buisness
- Wide applicability combined with fast runtimes makes linear programming quite popular

# Motivation for Semidefinite Programming

- Linear Programming is a common constrained optimization technique with uses in:
    - Math
    - Computer Science
    - Economics
    - Buisness
  - Wide applicability combined with fast runtimes makes linear programming quite popular
- 
- Semidefinite programming (SDP) expands upon the ideas of linear programming
    - SDP problems are more general
    - Widely used in combinatorial optimization problems
    - Many NP-Hard problems can be approximated well with SDP

# Motivation for a Linear Program

- Suppose that we have control over a set of variables:  
 $\vec{x} = [x_1, x_2, \dots, x_n]^\top$

# Motivation for a Linear Program

- Suppose that we have control over a set of variables:  
 $\vec{x} = [x_1, x_2, \dots, x_n]^\top$
- Where for each of these  $n$  variables we have an associated coefficient  $\vec{c} = [c_1, c_2, \dots, c_n]^\top$

# Motivation for a Linear Program

- Suppose that we have control over a set of variables:  
 $\vec{x} = [x_1, x_2, \dots, x_n]^\top$
- Where for each of these  $n$  variables we have an associated coefficient  $\vec{c} = [c_1, c_2, \dots, c_n]^\top$
- In the end we want to find the optimal value for the following equation:

$$\min \vec{c} \cdot \vec{x}$$

# Motivation for a Linear Program

$$\min C \cdot \vec{x}$$

- The problem is quite easy as is. What if each of these  $n$  variables corresponds to how much of a given product that we want to buy?
  - This would add additional constraints to what values  $\vec{x}$  could take on.

# Motivation for a Linear Program

$$\min C \cdot \vec{x}$$

- The problem is quite easy as is. What if each of these  $n$  variables corresponds to how much of a given product that we want to buy?
  - This would add additional constraints to what values  $\vec{x}$  could take on.
- Each variable must satisfy some constraint, we can express this as:

$$\vec{a}_1 \cdot \vec{x} \geq b_1$$

$$\vec{a}_2 \cdot \vec{x} \geq b_2$$

$$\vdots$$

$$\vec{a}_n \cdot \vec{x} \geq b_n$$

# Motivation for a Linear Program

$$\min \mathbf{C} \cdot \vec{x}$$

- The problem is quite easy as is. What if each of these  $n$  variables corresponds to how much of a given product that we want to buy?
  - This would add additional constraints to what values  $\vec{x}$  could take on.
- Each variable must satisfy some constraint, we can express this as:

$$\vec{a}_1 \cdot \vec{x} \geq b_1$$

$$\vec{a}_2 \cdot \vec{x} \geq b_2$$

$$\vdots$$

$$\vec{a}_n \cdot \vec{x} \geq b_n$$

- We can gather this into a single expression using a matrix

$$\mathbf{A}\vec{x} \geq \vec{b}$$

# Motivation for a Linear Program

$$\min \mathbf{C} \cdot \vec{x}$$

- The problem is quite easy as is. What if each of these  $n$  variables corresponds to how much of a given product that we want to buy?
  - This would add additional constraints to what values  $\vec{x}$  could take on.
- Each variable must satisfy some constraint, we can express this as:

$$\vec{a}_1 \cdot \vec{x} \geq b_1$$

$$\vec{a}_2 \cdot \vec{x} \geq b_2$$

$$\vdots$$

$$\vec{a}_n \cdot \vec{x} \geq b_n$$

- We can gather this into a single expression using a matrix

$$\mathbf{A}\vec{x} \geq \vec{b}$$

- Furthermore we often constraint  $\vec{x}$  to be non-negative:  $\vec{x} \geq 0$ .

# Standard Form for a Linear Program

$$\begin{array}{ll}\text{minimize} & \vec{c} \cdot \vec{x} \\ \text{subject to} & \mathbf{A}\vec{x} \geq \vec{b} \\ & \vec{x} \geq 0\end{array}$$

# Standard Form for a Linear Program

$$\begin{array}{ll}\text{minimize} & \vec{c} \cdot \vec{x} \\ \text{subject to} & \mathbf{A}\vec{x} \geq \vec{b} \\ & \vec{x} \geq 0\end{array}$$

- Where  $\vec{x}$  are the variables that we have control over
  - Example: Each variable of  $\vec{x}$  represents how much of a certain product to purchase

# Standard Form for a Linear Program

$$\begin{array}{ll}\text{minimize} & \vec{c} \cdot \vec{x} \\ \text{subject to} & \mathbf{A}\vec{x} \geq \vec{b} \\ & \vec{x} \geq 0\end{array}$$

- Where  $\vec{x}$  are the variables that we have control over
  - Example: Each variable of  $\vec{x}$  represents how much of a certain product to purchase
- $\vec{c}$  is a set of corresponding coefficients for the variables of  $\vec{x}$ 
  - Example: Each variable of  $\vec{c}$  corresponds to how much each product costs

# Standard Form for a Linear Program

$$\begin{array}{ll}\text{minimize} & \vec{c} \cdot \vec{x} \\ \text{subject to} & \mathbf{A}\vec{x} \geq \vec{b} \\ & \vec{x} \geq 0\end{array}$$

- Where  $\vec{x}$  are the variables that we have control over
  - Example: Each variable of  $\vec{x}$  represents how much of a certain product to purchase
- $\vec{c}$  is a set of corresponding coefficients for the variables of  $\vec{x}$ 
  - Example: Each variable of  $\vec{c}$  corresponds to how much each product costs
- $\min \vec{c} \cdot \vec{x}$  is the function we are trying to optimize
  - Example: We want to minimize the cost of buying our products

# Standard Form for a Linear Program

$$\begin{array}{ll}\text{minimize} & \vec{c} \cdot \vec{x} \\ \text{subject to} & \mathbf{A}\vec{x} \geq \vec{b} \\ & \vec{x} \geq 0\end{array}$$

- Where  $\vec{x}$  are the variables that we have control over
  - Example: Each variable of  $\vec{x}$  represents how much of a certain product to purchase
- $\vec{c}$  is a set of corresponding coefficients for the variables of  $\vec{x}$ 
  - Example: Each variable of  $\vec{c}$  corresponds to how much each product costs
- $\min \vec{c} \cdot \vec{x}$  is the function we are trying to optimize
  - Example: We want to minimize the cost of buying our products
- $\mathbf{A}\vec{x} \geq \vec{b}$  constraints on our solutions. Defines the feasible region.
  - Example: This could represent the minimum amount of products that we must buy

# Standard Form for a Linear Program

$$\begin{array}{ll}\text{minimize} & \vec{c} \cdot \vec{x} \\ \text{subject to} & \mathbf{A}\vec{x} \geq \vec{b} \\ & \vec{x} \geq 0\end{array}$$

- Where  $\vec{x}$  are the variables that we have control over
  - Example: Each variable of  $\vec{x}$  represents how much of a certain product to purchase
- $\vec{c}$  is a set of corresponding coefficients for the variables of  $\vec{x}$ 
  - Example: Each variable of  $\vec{c}$  corresponds to how much each product costs
- $\min \vec{c} \cdot \vec{x}$  is the function we are trying to optimize
  - Example: We want to minimize the cost of buying our products
- $\mathbf{A}\vec{x} \geq \vec{b}$  constraints on our solutions. Defines the feasible region.
  - Example: This could represent the minimum amount of products that we must buy

# Linear Programming to Semidefinite Programming

- Semidefinite programming (SDP) takes the concept that linear programming has with vectors and generalizes it to matrices.

Linear Programming	Semidefinite Programming
$\vec{x} \in \mathbb{R}^n$	$\mathbf{X} \in \mathbb{R}^{n \times n}$
$\vec{x} \geq 0$	$\mathbf{X} \succeq 0$
$\vec{c} \in \mathbb{R}^n$	$\mathbf{C} \in \mathbb{R}^{n \times n}$
$\min \vec{c} \cdot \vec{x}$	$\min \mathbf{C} \odot \mathbf{X}$
$\mathbf{A} \in \mathbb{R}^{n \times n}, \vec{b} \in \mathbb{R}^m$	$\mathbf{A}_i \in \mathbb{R}^{n \times n}, \vec{b} \in \mathbb{R}^m$
$\mathbf{A}\vec{x} \geq \vec{b}$	$\mathbf{A}_i \odot \mathbf{X} = b_i : i = 1, \dots, m$

# Linear Programming to Semidefinite Programming

- Semidefinite programming (SDP) takes the concept that linear programming has with vectors and generalizes it to matrices.

Linear Programming	Semidefinite Programming
$\vec{x} \in \mathbb{R}^n$	$\mathbf{X} \in \mathbb{R}^{n \times n}$
$\vec{x} \geq 0$	$\mathbf{X} \succeq 0$
$\vec{c} \in \mathbb{R}^n$	$\mathbf{C} \in \mathbb{R}^{n \times n}$
$\min \vec{c} \cdot \vec{x}$	$\min \mathbf{C} \odot \mathbf{X}$
$\mathbf{A} \in \mathbb{R}^{n \times n}, \vec{b} \in \mathbb{R}^n$	$\mathbf{A}_i \in \mathbb{R}^{n \times n}, \vec{b} \in \mathbb{R}^m$
$\mathbf{A}\vec{x} \geq \vec{b}$	$\mathbf{A}_i \odot \mathbf{X} = b_i : i = 1, \dots, m$

- The  $\odot$  is the Hadamard operator which is the sum of element wise multiplication:  $\mathbf{C} \odot \mathbf{X} = \sum_{i=1}^n \sum_{j=1}^n c_{i,j} x_{i,j}$
- $\mathbf{X} \succeq 0$  means that  $\mathbf{X}$  is positive semi-definite (PSD)

# Linear Programming to Semidefinite Programming

- In total we define a semidefinite program with the following:

$$\begin{array}{ll}\text{minimize} & \vec{c} \cdot \vec{x} \\ \text{subject to} & \mathbf{A}\vec{x} \geq \vec{b} \\ & \vec{x} \geq 0\end{array}$$

- In total we define a semidefinite program with the following:

$$\begin{array}{ll}\text{min} & \mathbf{C} \bullet \mathbf{X} \\ \text{subject to} & \mathbf{A}_i \bullet \mathbf{X} \geq b_i \quad i = 1, \dots, m \\ & \mathbf{X} \succeq 0\end{array}$$

# Semidefinite Programming Duality

- It is important to note the dual of an SDP problem which is:

$$\begin{array}{ll}\max & \sum_{i=1}^m z_i b_i \\ \text{such that} & \sum_{i=1}^m z_i \mathbf{A}_i + \mathbf{S} = \mathbf{C} \\ & \mathbf{S} \succeq 0\end{array}$$

# Semidefinite Programming Duality

- It is important to note the dual of an SDP problem which is:

$$\begin{array}{ll}\max & \sum_{i=1}^m z_i b_i \\ \text{such that} & \sum_{i=1}^m z_i \mathbf{A}_i + \mathbf{S} = \mathbf{C} \\ & \mathbf{S} \succeq 0\end{array}$$

- We are trying to find a set of scalars  $z_1, z_2, \dots, z_m$
- Where our objective function is  $\vec{z} \cdot \vec{b}$
- We also satisfy the constraint  $\sum_{i=1}^m z_i \mathbf{A}_i + \mathbf{S} = \mathbf{C}$  where  $\mathbf{A}_i$  and  $\mathbf{C}$  are from before.

# Semidefinite Programming Duality

- It is important to note the dual of an SDP problem which is:

$$\begin{array}{ll}\max & \sum_{i=1}^m z_i b_i \\ \text{such that} & \sum_{i=1}^m z_i \mathbf{A}_i + \mathbf{S} = \mathbf{C} \\ & \mathbf{S} \succeq 0\end{array}$$

- We are trying to find a set of scalars  $z_1, z_2, \dots, z_m$
- Where our objective function is  $\vec{z} \cdot \vec{b}$
- We also satisfy the constraint  $\sum_{i=1}^m z_i \mathbf{A}_i + \mathbf{S} = \mathbf{C}$  where  $\mathbf{A}_i$  and  $\mathbf{C}$  are from before.
- We know that  $\mathbf{S} \succeq 0$  which allows us to get the more intuitive:

$$\mathbf{C} - \sum_{i=1}^m z_i \mathbf{A}_i \succeq 0$$

- Pulling it all together:

$$\begin{array}{ll}\max & \sum_{i=1}^m z_i b_i \\ \text{such that} & \mathbf{C} - \sum_{i=1}^m z_i \mathbf{A}_i \succeq 0\end{array}$$

# Semidefinite Programming Runtime

- SDPs can be solved in polynomial time which makes them quite useful.
- One algorithm to solve them is Alizadeh's interior point method which runs in:

$$\tilde{O}(n^{3.5})$$

# Reviewing TSP

The Traveling Salesman Problem (TSP) is an optimization problem in which the objective is to find the shortest possible route for a salesman to visit a given set of cities, passing through each city exactly once, and returning to the starting city. It is a well-known NP-hard problem.

# Semidefinite Programming Methods for the Symmetric Traveling Salesman Problem , 1999

Let  $C \in \mathbb{R}^{n \times n}$  denote the matrix of edge costs. Let  $J$  denote the all-ones matrix, and  $e$  denote the all-ones vector.

$$\begin{aligned} & \text{minimize} && \frac{1}{2} \text{trace}(CX) \\ & \text{subject to} && Xe = 2e \\ & && X_{ii} = 0, \quad i = 1, \dots, n \\ & && 0 \leq X_{ij} \leq 1, \quad i, j = 1, \dots, n \\ & && 2I - X + \left(2 - 2 \cos \left(\frac{2\pi}{n}\right)\right)(J - I) \succeq 0 \\ & && X \text{ is a real, symmetric } n \times n \text{ matrix.} \end{aligned}$$

$X$  is a fractional adjacency matrix, meaning for  $e = \{i, j\}$ ,  $x_{ij} = x_{ji}$  is the proportion of edge  $e$  used.

# Integrity Gap And Running Time

# Of Nodes	SDP Time	BF Time	SDP Objective Value	BF Objective Value	Integrity Gap	Time Ratio
10	0.7101	0.0156	53224.4854	53228.3976	0.9999	45.519

# Low rank matrices

Given an incomplete matrix, can we recover the missing values?

		-1		
			1	
1	1	-1	1	-1
1				-1
		-1		

1	1	-1	1	-1
1	1	-1	1	-1
1	1	-1	1	-1
1	1	-1	1	-1
1	1	-1	1	-1

# Yes!

Given:

- The matrix is low rank\*
- We have enough sample data

Note: This does not apply to *all* low-rank matrices. But most.

# Yes!

Given:

- The matrix is low rank\*
- We have enough sample data

Note: This does not apply to *all* low-rank matrices. But most.

Why low-rank matrices?

# Why is this useful

- 1 **Netflix** has an incomplete set of user preferences based off their past watch history. Can they use this information to recommend new movies?
- 2 **Recommendation Engine:** The netflix problem can be extended to general recommendation engines where a vendor knows some of the user preferences.
- 3 **Images:** We will give an example of recovering a corrupted image using matrix completion

# Relaxing Matrix Completion to SDP

Suppose we have a low rank matrix  $\mathbf{M}$ . We have a set of location  $\Omega$  describing our sampling. That is, if  $(i, j) \in \Omega$ , we observe entry  $M_{ij}$ . Given  $\mathbf{M}$  is low rank, it seems resonable that we would like to solve the following optimization problem

# Relaxing Matrix Completetion to SDP

Suppose we have a low rank matrix  $\mathbf{M}$ . We have a set of location  $\Omega$  describing our sampling. That is, if  $(i, j) \in \Omega$ , we observe entry  $M_{ij}$ . Given  $\mathbf{M}$  is low rank, it seems resonable that we would like to solve the following optimization problem

$$\begin{array}{ll}\text{minimize} & \text{rank}(\mathbf{X}) \\ \text{subject to} & X_{ij} = M_{ij} \quad (i, j) \in \Omega \\ & \mathbf{X} \in \mathbb{R}^{n \times n}\end{array}$$

# Relaxing Matrix Completion to SDP

Suppose we have a low rank matrix  $\mathbf{M}$ . We have a set of location  $\Omega$  describing our sampling. That is, if  $(i, j) \in \Omega$ , we observe entry  $M_{ij}$ . Given  $\mathbf{M}$  is low rank, it seems reasonable that we would like to solve the following optimization problem

$$\begin{aligned} & \text{minimize} && \text{rank}(\mathbf{X}) \\ & \text{subject to} && X_{ij} = M_{ij} \quad (i, j) \in \Omega \\ & && \mathbf{X} \in \mathbb{R}^{n \times n} \end{aligned}$$

But...

Rank is not a convex. This turns out to be an NP-Hard Problem.

# Introduce the nuclear norm

## Nuclear Norm

The nuclear norm is a close approximation of the rank.

The nuclear norm of a matrix  $\mathbf{X}$  is defined as the sum of the eigenvalues.

$$\|\mathbf{X}\|_* = \sum_{k=1}^n \sigma_k \mathbf{X}$$

# Introduce the nuclear norm

## Nuclear Norm

The nuclear norm is a close approximation of the rank.

The nuclear norm of a matrix  $\mathbf{X}$  is defined as the sum of the eigenvalues.

$$\|\mathbf{X}\|_* = \sum_{k=1}^n \sigma_k \mathbf{X}$$

For a symmetric positive semi-definite (SPSD) matrices, the nuclear norm is equal to the trace.

# A better relaxation

What if our matrix is not SPSD

- We introduce two matrices  $\mathbf{W}_1$  and  $\mathbf{W}_2$

# A better relaxation

minimize  $\text{trace}(\mathbf{W}_1) + \text{trace}(\mathbf{W}_2)$

subject to  $X_{ij} = M_{ij} \quad (i, j) \in \Omega$

$$\begin{bmatrix} \mathbf{W}_1 & \mathbf{X} \\ \mathbf{X}^\top & \mathbf{W}_2 \end{bmatrix} \succeq 0$$
